Cheat Sheet: API's and Data Collection

Package/Method	Description		Code Example
		Syntax:	
Accessing element attribute	Access the value of a specific attribute of an HTML element.	1. 1	
		<pre>1. attribute = element[(attribute)]</pre>	
		Copied!	
		Example:	
		1. 1	
		<pre>1. href = link_element[(href)]</pre>	
		Copied!	
BeautifulSoup()	Parse the HTML content of a web page using BeautifulSoup. The parser type can vary based on the project.	Syntax:	
		1. 1	
		<pre>1. soup = BeautifulSoup(html, (html.parser))</pre>	
		Copied!	
		Example:	
		1. 1	
		1. html = (https://api.example.com/data) soup = BeautifulSoup(html	., (html.parser))
		Copied!	
delete()	Send a DELETE request to remove data or a resource from the server. DELETE requests delete a specified resource on the server.	Syntax:	
		1. 1	
		1. response = requests.delete(url)	
		Copied!	
		Example:	
		1. 1	
		<pre>1. response = requests.delete((https://api.example.com/delete))</pre>	
		Copied!	
find()	Find the first HTML element that matches the specified tag and attributes.	Syntax: 1. 1	
		 element = soup.find(tag, attrs) 	
		Copied!	
		Example:	
		1. 1	
		1. first_link = soup.find((a), {(class): (link)})	
		Copied!	

```
Syntax:
                                                                    1. 1
                                                                     1. elements = soup.find_all(tag, attrs)
                                                                   Copied!
                  Find all HTML elements that match the specified
find_all()
                  tag and attributes.
                                                                  Example:
                                                                    1. 1
                                                                     1. all_links = soup.find_all((a), {(class): (link)})
                                                                  Copied!
                                                                  Syntax:
                                                                    1. 1
                                                                     1. children = element.findChildren()
                                                                  Copied!
findChildren()
                  Find all child elements of an HTML element.
                                                                  Example:
                                                                    1. 1
                                                                     1. child_elements = parent_div.findChildren()
                                                                   Copied!
                                                                  Syntax:
                                                                    1. 1
                                                                     1. response = requests.get(url)
                  Perform a GET request to retrieve data from a
                  specified URL. GET requests are typically used
                                                                   Copied!
                  for reading data from an API. The response
get()
                  variable will contain the server's response, which Example:
                  you can process further.
                                                                     1. 1
                                                                     1. response = requests.get((https://api.example.com/data))
                                                                   Copied!
                                                                  Syntax:
                                                                    1. 1
                                                                     1. headers = {(HeaderName): (Value)}
                                                                   Copied!
                  Include custom headers in the request. Headers
                  can provide additional information to the server,
Headers
                                                                  Example:
                  such as authentication tokens or content types.
                                                                    1. 1
                                                                    1. base_url = (https://api.example.com/data) headers = {(Authorization): (Bearer YOUR_TOKEN)} response = requests.get(base_url, headers=headers)
                                                                   Copied!
                                                                  Syntax:
                                                                     1. 1
                  Import the necessary Python libraries for web
Import Libraries
                   scraping.
                                                                    1. from bs4 import BeautifulSoup
                                                                   Copied!
```

```
Syntax:
                                                                     1. 1
                                                                     1. data = response.json()
                   Parse JSON data from the response. This extracts Copied!
                   and works with the data returned by the API. The
                   response.json() method converts the JSON
json()
                                                                   Example:
                   response into a Python data structure (usually a
                                                                     1. 1
                   dictionary or list).
                                                                     2. 2
                                                                     1. response = requests.get((https://api.example.com/data))
                                                                     2. data = response.json()
                                                                   Copied!
                                                                   Syntax:
                                                                     1. 1
                                                                     1. sibling = element.find_next_sibling()
                                                                   Copied!
                   Find the next sibling element in the DOM.
next sibling()
                                                                   Example:
                                                                     1. 1
                                                                     1. next_sibling = current_element.find_next_sibling()
                                                                   Copied!
                                                                   Syntax:
                                                                     1. 1
                                                                     1. parent = element.parent
                                                                   Copied!
                   Access the parent element in the Document Object
parent
                   Model (DOM).
                                                                   Example:
                                                                     1. 1
                                                                     1. parent_div = paragraph.parent
                                                                   Copied!
                                                                   Syntax:
                                                                     1. 1
                                                                     1. response = requests.post(url, data)
                   Send a POST request to a specified URL with
                                                                   Copied!
                   data. Create or update POST requests using
                   resources on the server. The data parameter
post()
                                                                   Example:
                   contains the data to send to the server, often in
                   JSON format.
                                                                     1. 1
                                                                     1. response = requests.post((https://api.example.com/submit), data={(key): (value)})
                                                                   Copied!
                   Send a PUT request to update data on the server. Syntax:
put()
                   PUT requests are used to update an existing
                                                                     1. 1
                   resource on the server with the data provided in
                   the data parameter, typically in JSON format.

    response = requests.put(url, data)
```

```
Example:
                                                                    1. 1
                                                                    1. response = requests.put((https://api.example.com/update), data={(key): (value)})
                                                                   Copied!
                                                                  Syntax:
                                                                    1. 1
                                                                    1. params = {(param_name): (value)}
                                                                  Copied!
                  Pass query parameters in the URL to filter or
                                                                  Example:
Query parameters
                 customize the request. Query parameters specify
                  conditions or limits for the requested data.
                                                                    1. 1
                                                                    2. 2
                                                                    3.3
                                                                    1. base_url = "https://api.example.com/data"
                                                                     2. params = {"page": 1, "per_page": 10}
                                                                     3. response = requests.get(base_url, params=params)
                                                                   Copied!
                                                                  Syntax:
                                                                    1. 1

    element = soup.select(selector)

                                                                   Copied!
                  Select HTML elements from the parsed HTML
select()
                  using a CSS selector.
                                                                  Example:
                                                                    1. 1
                                                                    1. titles = soup.select((h1))
                                                                  Copied!
                                                                  Syntax:

    response.status_code

                                                                   Copied!
                  Check the HTTP status code of the response. The
                  HTTP status code indicates the result of the
                                                                  Example:
status code
                  request (success, error, redirection). Use the HTTP
                  status codeIt can be used for error handling and
                                                                    1. 1
                                                                    2. 2
                  decision-making in your code.
                                                                    3. 3
                                                                    1. url = "https://api.example.com/data"
                                                                    2. response = requests.get(url)
                                                                     3. status_code = response.status_code
tags for find() and Specify any valid HTML tag as the tag parameter Tag Example:
                  to search for elements of that type. Here are some
find all()
                                                                    1. 1
                  common HTML tags that you can use with the tag
                                                                    2. 2
                  parameter.
                                                                     3.3
```
